

Dynamic Programming

Algorithm design strategies seen thus far:

- Brute force — exhaustively consider through all possibilities
- Divide and conquer — examples: binary search, mergesort, quicksort
- Greedy algorithm — examples: Prim’s algorithm for minimum spanning tree, Dijkstra’s algorithm for single source shortest path
- Dynamic programming — this lecture

1 Definitions

Dynamic Programming is an algorithmic paradigm: It is used when the solution can be recursively described in terms of solutions to subproblems (optimal substructure).

Unlike divide and conquer, where subproblems are independent and solved separately, dynamic programming applies when subproblems *overlap*—i.e., the same subproblems recur multiple times. DP solves each subproblem once and stores the result for reuse, thereby avoiding redundant computation.

Memoization: Algorithm finds solutions to subproblems and stores them in memory for later use. More efficient than brute-force methods, which solve the same subproblems over and over again.

Typically solved bottom-up, building a table of solved subproblems that are used to solve larger ones.

The word programming is historical, and was chosen by Richard Bellman to describe a program in the sense of a schedule.

We study a number of examples to see Dynamic programming in action.

2 Fibonacci series

The Fibonacci series can be recursively expressed as:

$$F_n = F_{n-1} + F_{n-2}$$

with $F_0 = 0$, and $F_1 = 1$.

$$F_2 = F_1 + F_0, \quad F_3 = F_2 + F_1, \text{ and so on}$$

```
int fibonacci(int n) {  
    if (n == 0) return 0;  
    if (n == 1) return 1;  
    return fibonacci(n-1) + fibonacci(n-2);  
}
```

The naive recursive solution has exponential in n run time — $O(c^n)$ where c is a constant. The exponential run time happens because of repeatedly solving the same subproblems.

Dynamic programming solution with memoization — Top down approach

Idea: Cache (memoize) computed results. For any new computation, check cache to see if it holds the result, or else recurse.

```

vector<int> A(n+1, -1); // For memoization
A[0] = 0;
A[1] = 1;

int fibonacci(int n) {
    if (A[n] != -1) // Result in cache
        return A[n];
    else
        A[n] = fibonacci(n-1) + fibonacci(n-2); // Cache result
    return A[n];
}

```

Dynamic programming solution with tabulation — Bottom up approach

Idea: Build a table of partial results from the bottom up.

```

int fibonacci(int n) {
    vector<int> A(n+1);
    A[0] = 0;
    A[1] = 1;
    for (int i = 2; i <= n; i++) {
        A[i] = A[i-1] + A[i-2];
    }
    return A[n];
}

```

Time: $O(n)$ Space: $O(n)$ Turns out you don't need a whole array. All you need is the last two numbers (two variables). So the space required is only $O(1)$.

3 Rod cutting problem

You are given a rod of size $n > 0$, it can be cut into any number of pieces k ($k \leq n$). Price for each piece of size i is represented as $p(i)$ and maximum revenue from a rod of size i is $r(i)$ (could be split into multiple pieces). Find maximum $r(n)$ for the rod of size n .

For example, here's an array of prices where the array index + 1 indicates rod length:

$$p = \{1, 5, 8, 9, 10, 17, 17, 20\}$$

The price of a rod of length 2 is 5.

Example: What is the best price for a rod of length 3?

- Break into 3 pieces of length 1: \$3

- Break into 1 piece of length 2 and 1 piece of length 1: \$6
- Don't break the rod: \$8

Best price: don't cut the rod.

Example for rod of length 4: breaking up into 2 and 2 yields \$10.

Let's build some intuition:

- Length 1: only possibility price \$1
- Length 2: possibilities (1,1)(cut) or (0,2) (uncut) $\rightarrow \max(\$2, \$5) = \$5$
- Length 3: possibilities (0,3), (1,2) $\rightarrow \max(\$8, \$6) = \$8$
- Length 4: (0,4), (1,3), (2,2) $\rightarrow \max(\$9, \$9, \$10) = \10

Note how we use the optimal solutions of smaller subproblems, and how the subproblems repeat.

General algorithm:

```
int rodCutting(const vector<int>& P, int n) {
    vector<int> maxP(n+1, 0);
    for (int i = 1; i <= n; i++) {
        int maxVal = P[i-1];
        for (int j = 1; j <= i/2; j++) {
            maxVal = max(maxVal, maxP[j] + maxP[i-j]);
        }
        maxP[i] = maxVal;
    }
    return maxP[n];
}
```

Complexity: $O(n^2)$

4 Max sum of non adjacent elements

Given an array of positive integers, find the maximum sum of non adjacent elements.

Example: [75, 105, 120, 75, 90, 135] Ans: $330 = 75 + 120 + 135$

Thinking Through the Maximum Sum of Non-Adjacent Elements

Let us think about the problem step by step:

If we can solve a smaller problem, can we use that to construct the solution of a larger one?

- Input: [75]
Best sum: 75
- Input: [75, 105]
Best sum: $\max(75, 105) = 105$
- Input: [75, 105, 120]
If we include 120, then the best is $75 + 120 = 195$.
If we exclude 120, the best is 105.
Thus, $\max(195, 105) = 195$. We would include 120.
- Running total so far: [75, 105, 195]
- Next input element: 75
Including this 75: $105 + 75 = 180$
Excluding: 195
Best: $\max(180, 195) = 195$

- Running total so far: [75, 105, 195, 195]
- Next element: 90
Including: $195 + 90 = 285$
Excluding: 195
Best: 285
- Running total so far: [75, 105, 195, 195, 285]
- Next element: 135
Including: $195 + 135 = 330$
Excluding: 285
Best: $\max(330, 285) = 330$
- Final maximum sums: [75, 105, 195, 195, 285, 330]

General approach:

```
int maxSumNonAdj(const vector<int>& in) {
    int n = in.size();
    vector<int> maxSum(n);
    maxSum[0] = in[0];
    maxSum[1] = max(in[0], in[1]);
    for (int i = 2; i < n; i++) {
        maxSum[i] = max(maxSum[i-1], maxSum[i-2] + in[i]);
    }
    return maxSum[n-1];
}
```

5 Levenshtein Distance (Edit distance)

The Levenshtein distance between two words is the minimum number of single-character edits (insertions, deletions, or substitutions) required to change one word to another. Each of these operations has unit cost.

For example, the Levenshtein distance between kitten and sitting is 3.

kitten → sitten	(substitute k for s)
sitten → sittin	(substitute e for i)
sittin → sitting	(insert g at the end)
Total operations = 3	

This problem exhibits **optimal substructure** — it can be broken down into solving simpler subproblems.

Problem Definition

Given two strings $X[1 \dots m]$ and $Y[1 \dots n]$, compute the minimum number of edit operations to convert X into Y .

Subproblem

Convert substring $X[1 \dots i]$ to $Y[1 \dots j]$ using edit operations.

Recursive Cases (Top-Down)

Case 1: One of the substrings is empty.

If X is empty, insert all remaining characters from Y , and vice versa.

Example: ("", "ABC") → ("ABC", "ABC")

Cost: 3

Case 2: Last characters of X and Y match.

No edit needed; recurse on $X[1 \dots i - 1]$ and $Y[1 \dots j - 1]$.

Example: ("ACC", "ABC") \rightarrow ("AC", "AB")

Cost: 0

Case 3: Last characters differ — consider three operations and take the minimum:

- **Delete from X :** recurse on $X[1 \dots i - 1]$, $Y[1 \dots j]$

Example: ("ABA", "ABC") \rightarrow ("AB", "ABC")

- **Delete from Y :** recurse on $X[1 \dots i]$, $Y[1 \dots j - 1]$

Example: ("ABA", "ABC") \rightarrow ("ABA", "AB")

- **Substitute:** recurse on $X[1 \dots i - 1]$, $Y[1 \dots j - 1]$

Example: ("ABA", "ABC") \rightarrow ("ABC", "ABC")

Recurrence Relation

$$\text{dist}[i][j] = \begin{cases} \max(i, j) & \text{if } \min(i, j) = 0 \\ \text{dist}[i - 1][j - 1] & \text{if } X[i] = Y[j] \\ 1 + \min\{\text{dist}[i - 1][j], \text{dist}[i][j - 1], \text{dist}[i - 1][j - 1]\} & \text{if } X[i] \neq Y[j] \end{cases}$$

Time Complexity

$$\mathcal{O}(mn)$$

where m and n are the lengths of strings X and Y . Brute-force approaches are exponential, but dynamic programming reduces this to polynomial time.

		s	i	t	t	i	n	g
	0	1	2	3	4	5	6	7
k	1	1	2	3	4	5	6	7
i	2	2	1	2	3	4	5	6
t	3	3	2	1	2	3	4	5
t	4	4	3	2	1	2	3	4
e	5	5	4	3	2	2	3	4
n	6	6	5	4	3	3	2	3

Table 1: Levenshtein Distance Matrix for **kitten** and **sitting**. Edit distance = 3

6 Knapsack problem (1/0)

Optimization Problem

Input:

- n items, each with:
 - value V_i (non-negative)
 - weight W_i (non-negative, integral)
- capacity W (a non-negative integer)

Output: Select a subset of items that maximizes the total value without exceeding the capacity W .

Bottom-Up Dynamic Programming Approach

We define a DP table $V[i][j]$ to represent the maximum value achievable using the first i items and capacity j . We construct this table using the recurrence:

- **Case 1:** Skip the i -th item

$$V[i][j] = V[i-1][j]$$

- **Case 2:** Include the i -th item, provided $j \geq W_i$

$$V[i][j] = V[i-1][j - W_i] + V_i$$

- **Final recurrence:**

$$V[i][j] = \max(V[i-1][j], V[i-1][j - W_i] + V_i) \quad (\text{if } j \geq W_i)$$

- **Boundary conditions:**

$$V[0][j] = 0 \quad (\text{no items}) \quad V[i][0] = 0 \quad (\text{zero capacity})$$

Time Complexity: $\mathcal{O}(nW)$, where n is the number of items and W is the maximum knapsack capacity (assumed to be an integer). Given items with values V_i and weights W_i , capacity W , maximize value without exceeding W .

```
int knapsack(const vector<int>& V, const vector<int>& W, int capacity) {
    int n = V.size();
    vector<vector<int>> dp(n+1, vector<int>(capacity+1, 0));
    for (int i = 1; i <= n; i++) {
        for (int w = 0; w <= capacity; w++) {
            if (W[i-1] <= w)
                dp[i][w] = max(dp[i-1][w], dp[i-1][w - W[i-1]] + V[i-1]);
            else
                dp[i][w] = dp[i-1][w];
        }
    }
    return dp[n][capacity];
}
```

Complexity: $\mathcal{O}(nW)$

Example:

$W = 6$
 $v_1 = 3, w_1 = 4$
 $v_2 = 2, w_2 = 3$
 $v_3 = 4, w_3 = 2$
 $v_4 = 4, w_4 = 3$

Items \ Weights	0	1	2	3	4	5	6
0	0	0	0	0	0	0	0
1	0	0	0	0	3	3	3
2	0	0	0	2	3	3	3
3	0	0	4	4	4	6	7
4	0	0	4	4	4	8	8

Table 2: Value matrix for 0/1 Knapsack Problem. Rows represent items and columns represent weight capacities.

To figure out which items were included in the knapsack, backtrack

Start from the lower right corner $V[4][6]$

Was this value gotten from taking or not taking item 4? Since $V[3][6] \neq V[4][6]$, item 4 was chosen.

$V[4][6]$ was obtained from $V[3][3]$ (Subtracting weight of item 4)

Again $V[3][3] \neq V[2][3]$, so item 3 was chosen.

$V[3][3]$ was obtained from $V[2][1]$ (subtracting weight of item 3)

Since $V[2][1]$ has no residual capacity to include any more items, search terminates.
